```
diagnosis <-as.factor(wisc.df$diagnosis)
wisc.data <- wisc.df[,-1]</pre>
```

Q1. How mnay observations are in this dataset?

```
nrow(wisc.df)
```

[1] 569

There are 569 people in this data set being observed

Q2. How many of the observations have a malignant diagnosis?

```
B M
357 212

There are 212 people with the malignant diagnosis. Or you could do it this way
sum(wisc.df$diagnosis=="M")

[1] 212
Q3. How many variables/features in the data are suffixed with _mean?
x <- colnames(wisc.df)
length(grep("mean", x,))</pre>
```

[1] 10

Principal Component Analysis

We need to scale our input data beofre PCA as some of the columns are measured in terns of very different units with different means and different variances. The upshot here is we sert scale=TRUE argument to prcomp()

```
# Check column means and standard deviations
colMeans(wisc.data)
```

```

```
plot(wisc.pr$x[,1], wisc.pr$x[,2], col=diagnosis)
```

Q4. From your results, what proportion of the original variance is captured by the first principal components (PC1)?

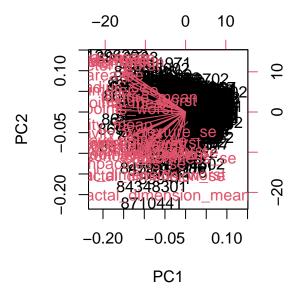

44.27% of the original varience is captured by the first principle component. >Q5. How many principal components (PCs) are required to describe at least 70% of the original variance in the data?

PC1, PC2, PC3

Q6. How many principal components (PCs) are required to describe at least 90% of the original variance in the data?

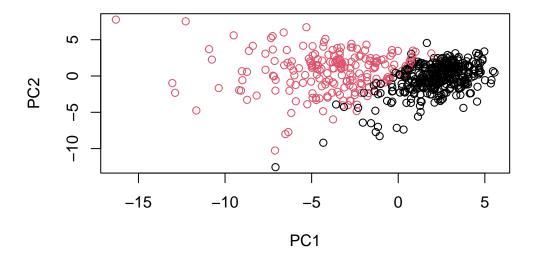

PC1, PC2, PC3, PC4, PC5, PC6, PC7

biplot(wisc.pr)

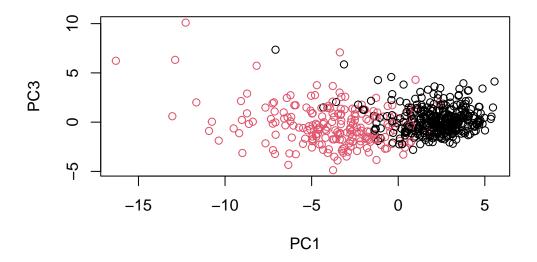

Q7. What stands out to you about this plot? Is it easy or difficult to understand? Why?

It's a hot mess, it's hard to read and everything is overlapping.

Q8. Generate a similar plot for principal components 1 and 3. What do you notice about these plots?

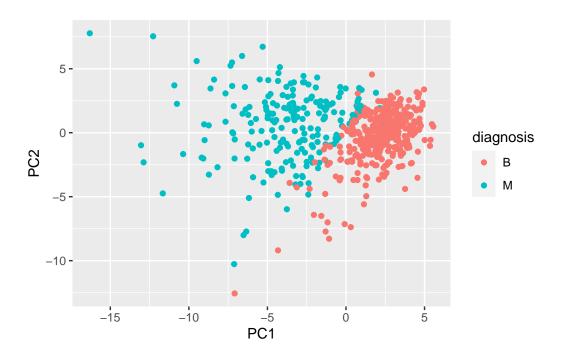

The first plot has a cleaner cut and has cleaner clusters, while this one has less clean data

```
# Create a data.frame for ggplot
df <- as.data.frame(wisc.pr$x)
df$diagnosis <- diagnosis

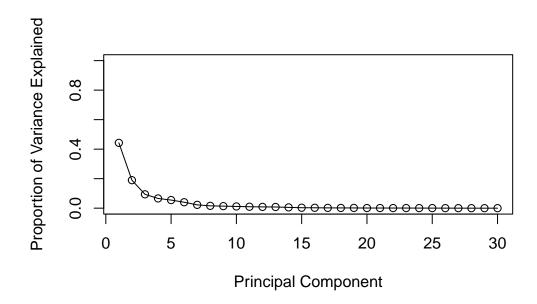

# Load the ggplot2 package
library(ggplot2)

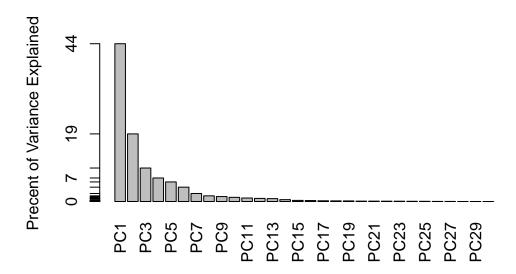

# Make a scatter plot colored by diagnosis
ggplot(df) +
   aes(PC1, PC2, col=diagnosis,) +
   geom_point()</pre>
```

```
# Calculate variance of each component
pr.var <- wisc.pr$sdev^2
head(pr.var)</pre>
```

[1] 13.281608 5.691355 2.817949 1.980640 1.648731 1.207357

Optional:

```
library(factoextra)
```

Welcome! Want to learn more? See two factoextra-related books at https://goo.gl/ve3WBa

```
fviz_eig(wisc.pr, addlabels = TRUE)
```

Q9. For the first principal component, what is the component of the loading vector (i.e. wisc.pr\$rotation[,1]) for the feature concave.points_mean?

```
wisc.pr$rotation[,1]["concave.points_mean"]
```

concave.points_mean -0.2608538

Q10. What is the minimum number of principal components required to explain 80% of the variance of the data?

PC1, PC2, PC3, PC4, PC5 (so five of them)

Hierarchical Clustering

```
# Scale the wisc.data data using the "scale()" function
data.scaled <- scale(wisc.data)

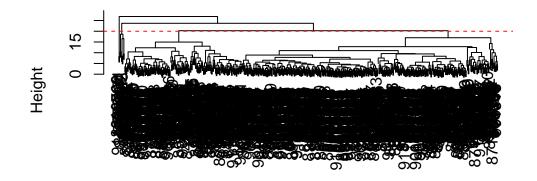

data.dist <- dist(data.scaled)</pre>
```

```
wisc.hclust <- hclust(data.dist, method="complete")</pre>
```

Q11. Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters?

```
plot(wisc.hclust)
abline(h=20, col="red", lty=2)
```

Cluster Dendrogram

data.dist hclust (*, "complete")

```
wisc.hclust.clusters <- cutree(wisc.hclust, k=4)
table(wisc.hclust.clusters, diagnosis)</pre>
```

diagnosis wisc.hclust.clusters B M 1 12 165 2 2 5 3 343 40 4 0 2

Q12. Can you find a better cluster vs diagnoses match by cutting into a different number of clusters between 2 and 10?

4 is the best cluster number, it gives us the 2 clusters that we need and separates they into mostly benine and mostley malignent. Too many clusters separates them into usless clusters.

Q13. Which method gives your favorite results for the same data.dist dataset? Explain your reasoning.

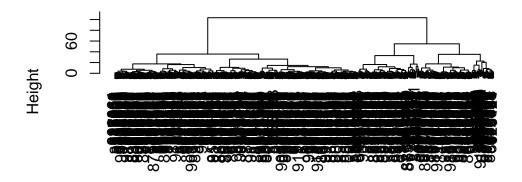

ward.D2 is my favorite because it balances clusters and minimizes the varience making the clusters well defined.

##4 K-means clustering

##5. Combining methods This approach will take not original data but our PCA results and work with them.

```
d <- dist(wisc.pr$x[,1:3])
wisc.pr.hclust <- hclust(d, method= "ward.D2")
plot(wisc.pr.hclust)</pre>
```

Cluster Dendrogram

d hclust (*, "ward.D2")

Generate 2 cluster groups from this helust object.

```
grps <- cutree(wisc.pr.hclust, k=2)
grps</pre>
```

plot(wisc.pr\$x[,1], wisc.pr\$x[,2], col=grps)

table(grps)

grps

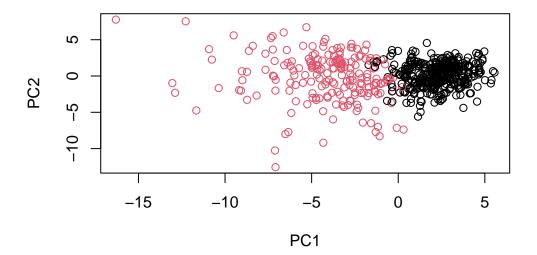

```
g <- as.factor(grps)
levels(g)

[1] "1" "2"

g <- relevel(g,2)
levels(g)

[1] "2" "1"

# Plot using our re-ordered factor
plot(wisc.pr$x[,1:2], col=g)</pre>
```

```
## Use the distance along the first 7 PCs for clustering i.e. wisc.prx[, 1:7] wisc.pr.hclust <- hclust (dist(wisc.prx[,1:7]), method="ward.D2")

wisc.pr.hclust.clusters <- cutree(wisc.pr.hclust, k=2)
```

Q15. How well does the newly created model with four clusters separate out the two diagnoses?

```
# Compare to actual diagnoses
table(wisc.pr.hclust.clusters, diagnosis)
```

```
diagnosis
wisc.pr.hclust.clusters B M
1 28 188
2 329 24
```

It separates them out pretty well and is clear.
